---

### 3.1 EXTENDING THE SIMPLY TYPED $\lambda$ -CALCULUS

We will add now special syntax for some terms and types, such as pairs, unions and unit types. This syntax will make our  $\lambda$ -calculus more expressive, but the unification and type inference algorithms will continue to work. The previous proofs and algorithms can be extended to cover all the new cases.

**Definition 26** (Simple types II). The new set of **simple types** is given by the following BNF

$$\text{Type} ::= \iota \mid \text{Type} \rightarrow \text{Type} \mid \text{Type} \times \text{Type} \mid \text{Type} + \text{Type} \mid 1 \mid 0,$$

where  $\iota$  would be any *basic type*.

That is to say that, for any given types  $A, B$ , there exists a product type  $A \times B$ , consisting of the pairs of elements where the first one is of type  $A$  and the second one of type  $B$ ; there exists the union type  $A + B$ , consisting of a disjoint union of tagged terms from  $A$  or  $B$ ; an unit type  $1$  with only an element, and an empty or void type  $0$  without inhabitants. The raw typed  $\lambda$ -terms are extended to use these new types.

**Definition 27** (Raw typed lambda terms II). The new set of raw **typed lambda terms** is given by the BNF

$$\begin{aligned} \text{Term} ::= & x \mid \text{TermTerm} \mid \lambda x. \text{Term} \mid \\ & \langle \text{Term}, \text{Term} \rangle \mid \pi_1 \text{Term} \mid \pi_2 \text{Term} \mid \\ & \text{inl Term} \mid \text{inr Term} \mid \text{case Term of Term; Term} \mid \\ & \text{abort Term} \mid * \end{aligned}$$

The use of these new terms is formalized by the following extended set of typing rules.

1. The (*var*) rule simply makes explicit the type of a variable from the context.

$$(\text{var}) \frac{}{\Gamma, x : A \vdash x : A}$$

2. The  $(abs)$  gives the type of a  $\lambda$ -abstraction as the type of functions from the variable type to the result type. It acts as a constructor of function terms.

$$(abs) \frac{\Gamma, x : A \vdash M : B}{\Gamma \vdash \lambda x. M : A \rightarrow B}$$

3. The  $(app)$  rule gives the type of a well-typed application of a lambda term. A term  $f : A \rightarrow B$  applied to a term  $a : A$  is a term of type  $B$ . It acts as a destructor of function terms.

$$(app) \frac{\Gamma \vdash f : A \rightarrow B \quad \Gamma \vdash a : A}{\Gamma \vdash fa : B}$$

4. The  $(pair)$  rule gives the type of a pair of elements. It acts as a constructor of pair terms.

$$(pair) \frac{\Gamma \vdash a : A \quad \Gamma \vdash b : B}{\Gamma \vdash \langle a, b \rangle : A \times B}$$

5. The  $(\pi_1)$  rule extracts the first element from a pair. It acts as a destructor of pair terms.

$$(\pi_1) \frac{\Gamma \vdash m : A \times B}{\Gamma \vdash \pi_1 m : A}$$

6. The  $(\pi_2)$  rule extracts the second element from a pair. It acts as a destructor of pair terms.

$$(\pi_2) \frac{\Gamma \vdash m : A \times B}{\Gamma \vdash \pi_2 m : B}$$

7. The  $(inl)$  rule creates a union type from the left side type of the sum. It acts as a constructor of union terms.

$$(inl) \frac{\Gamma \vdash a : A}{\Gamma \vdash inl a : A + B}$$

8. The  $(inr)$  rule creates a union type from the right side type of the sum. It acts as a constructor of union terms.

$$(inr) \frac{\Gamma \vdash b : B}{\Gamma \vdash inr b : A + B}$$

9. The  $(case)$  rule extracts a term from an union and applies the appropriate deduction on any of the two cases

$$(case) \frac{\Gamma \vdash m : A + B \quad \Gamma, a : A \vdash n : C \quad \Gamma, b : B \vdash p : C}{\Gamma \vdash (case m \text{ of } [a].n; [b].p) : C}$$

Note that we write  $[a].n$  and  $[b].p$  to indicate that  $n$  and  $p$  depend on  $a$  and  $b$  respectively.

10. The  $(*)$  rule simply creates the only element of 1. It is a constructor of the unit type.

$$(*) \frac{}{\Gamma \vdash * : 1}$$

11. The  $(abort)$  rule extracts a term of any type from the void type.

$$(abort) \frac{\Gamma \vdash M : 0}{\Gamma \vdash abort_A M : A}$$

The abort function must be understood as the unique function going from the empty set to any given set.

The  $\beta$ -reduction of terms is defined the same way as for the untyped  $\lambda$ -calculus; except for the inclusion of  $\beta$ -rules governing the new terms, each for every new destruction rule.

1. Function application,  $(\lambda x.M)N \rightarrow_\beta M[N/x]$ .
2. First projection,  $\pi_1 \langle M, N \rangle \rightarrow_\beta M$ .
3. Second projection,  $\pi_2 \langle M, N \rangle \rightarrow_\beta N$ .
4. Case rule,  $(\text{case } m \text{ of } [a].N; [b].P) \rightarrow_\beta Na$  if  $m$  is of the form  $m = \text{inl } a$ ; and  $(\text{case } m \text{ of } [a].N; [b].P) \rightarrow_\beta Pb$  if  $m$  is of the form  $m = \text{inr } b$ .

On the other side, new  $\eta$ -rules are defined, each for every new construction rule.

1. Function extensionality,  $\lambda x.Mx \rightarrow_\eta M$ .
2. Definition of product,  $\langle \pi_1 M, \pi_2 M \rangle \rightarrow_\eta M$ .
3. Uniqueness of unit,  $M \rightarrow_\eta *$ .
4. Case rule,  $(\text{case } m \text{ of } [a].P[\text{inl } a/c]; [b].P[\text{inr } b/c]) \rightarrow_\eta P[m/c]$ .

### 3.2 NATURAL DEDUCTION

The natural deduction is a logical system due to Gentzen. We introduce it here following [Sel13] and [Wad15]. Its relationship with the simply-typed lambda calculus will be made explicit in the [next section](#).

We will use the logical binary connectives  $\rightarrow, \wedge, \vee$ , and two given propositions,  $\top, \perp$  representing the trivially true and false propositions, respectively. The rules defining natural deduction come in pairs; there are introductors and eliminators for every connective. Every introducer uses a set of assumptions to generate a formula and every eliminator gives a way to extract precisely that set of assumptions.

1. Every axiom on the context can be used.

$$\frac{}{\Gamma, A \vdash A} (Ax)$$

2. Introduction and elimination of the  $\rightarrow$  connective. Note that the elimination rule corresponds to *modus ponens* and the introduction rule corresponds to the *deduction theorem*.

$$\frac{\Gamma, A \vdash B}{\Gamma \vdash A \rightarrow B} (I_{\rightarrow}) \quad \frac{\Gamma \vdash A \rightarrow B \quad \Gamma \vdash A}{\Gamma \vdash B} (E_{\rightarrow})$$

3. Introduction and elimination of the  $\wedge$  connective. Note that the introduction in this case takes two assumptions, and there are two different elimination rules.

$$\frac{\Gamma \vdash A \quad \Gamma \vdash B}{\Gamma \vdash A \wedge B} (I_{\wedge}) \quad \frac{\Gamma \vdash A \wedge B}{\Gamma \vdash A} (E_{\wedge}^1) \quad \frac{\Gamma \vdash A \wedge B}{\Gamma \vdash B} (E_{\wedge}^2)$$

4. Introduction and elimination of the  $\vee$  connective. Here, we need two introduction rules to match the two assumptions we use on the eliminator.

$$\frac{\Gamma \vdash A}{\Gamma \vdash A \vee B} (I_{\vee}^1) \quad \frac{\Gamma \vdash B}{\Gamma \vdash A \vee B} (I_{\vee}^2) \quad \frac{\Gamma \vdash A \vee B \quad \Gamma, A \vdash C \quad \Gamma, B \vdash C}{\Gamma \vdash C} (E_{\vee})$$

5. Introduction for  $\top$ . It needs no assumptions and, consequently, there is no elimination rule for it.

$$\frac{}{\Gamma \vdash \top} (I_{\top})$$

6. Elimination for  $\perp$ . It can be eliminated in all generality, and, consequently, there are no introduction rules for it. This elimination rule represents the "*ex falsum quodlibet*" principle that says that falsity implies anything.

$$\frac{\Gamma \vdash \perp}{\Gamma \vdash C} (E_{\perp})$$

Proofs on natural deduction are written as deduction trees, and they can be simplified according to some simplification rules, which can be applied anywhere on the deduction tree. On these rules, a chain of dots represents any given part of the deduction tree.

1. An implication and its antecedent can be simplified using the antecedent directly on the implication.

$$\begin{array}{c} [A] \\ \vdots^1 \\ B \\ \hline A \rightarrow B \\ \hline B \\ \vdots \end{array} \quad \begin{array}{c} \vdots^2 \\ A \\ \vdots^1 \\ B \\ \vdots \end{array} \quad \Rightarrow \quad \begin{array}{c} \vdots^2 \\ A \\ \vdots^1 \\ B \\ \vdots \end{array}$$

2. The introduction of an unused conjunction can be simplified as

$$\begin{array}{c} \vdots^1 \quad \vdots^2 \\ A \quad B \\ \hline A \wedge B \\ \hline A \\ \vdots \end{array} \quad \Rightarrow \quad \begin{array}{c} \vdots^1 \\ A \\ \vdots \end{array}$$

and, similarly, on the other side as

$$\frac{\frac{\frac{\vdots^1}{A} \quad \frac{\vdots^2}{B}}{A \wedge B} \quad \frac{B}{\vdots}}{\vdots} \Rightarrow \frac{\vdots^2}{B}$$

3. The introduction of a disjunction followed by its elimination can be also simplified

$$\frac{\frac{\frac{\vdots^1}{A}}{A \vee B} \quad \frac{\frac{[A] \quad \vdots^2}{C} \quad \frac{[B] \quad \vdots^3}{C}}{C}}{\vdots} \Rightarrow \frac{\frac{\vdots^1}{A} \quad \frac{\vdots^2}{C}}{C}$$

and a similar pattern is used on the other side of the disjunction

$$\frac{\frac{\frac{\vdots^1}{B}}{A \vee B} \quad \frac{\frac{[A] \quad \vdots^2}{C} \quad \frac{[B] \quad \vdots^3}{C}}{C}}{\vdots} \Rightarrow \frac{\frac{\vdots^1}{B} \quad \frac{\vdots^3}{C}}{C}$$

### 3.3 PROPOSITIONS AS TYPES

In 1934, Curry observed in [Cur34] that the type of a function ( $A \rightarrow B$ ) could be read as an implication and that the existence of a function of that type was equivalent to the provability of the proposition. Previously, the **Brouwer-Heyting-Kolmogorov interpretation** of intuitionistic logic had given a definition of what it meant to be a proof of an intuitionistic formula, where a proof of the implication ( $A \rightarrow B$ ) was a function converting a proof of  $A$  into a proof of  $B$ . It was not until 1969 that Howard pointed a deep correspondence between the simply-typed  $\lambda$ -calculus and the natural deduction at three levels

1. propositions are types.
2. proofs are programs.

3. simplification of proofs is the evaluation of programs.

In the case of simply typed  $\lambda$ -calculus and natural deduction, the correspondence starts when we describe the following one-to-one relation between types and propositions.

Types	Propositions
Unit type (1)	Truth ( $\top$ )
Product type ( $\times$ )	Conjunction ( $\wedge$ )
Union type ( $+$ )	Disjunction ( $\vee$ )
Function type ( $\rightarrow$ )	Implication ( $\rightarrow$ )
Empty type (0)	False ( $\perp$ )

Where, in particular, the negation of a proposition  $\neg A$  is interpreted as the fact that that proposition implies falsehood,  $A \rightarrow \perp$ ; and its corresponding type is a function from the type  $A$  to the empty type,  $A \rightarrow 0$ .

Now it is easy to notice that every **deduction rule** for a proposition has a correspondence with a **typing rule**. The only distinction between them is the appearance of  $\lambda$ -terms on the first set of rules. As every typing rule results on the construction of a particular kind of  $\lambda$ -term, they can be interpreted as encodings of proof in the form of derivation trees. That is, terms are proofs of the propositions represented by their types.

*Example 2* (Curry-Howard correspondence example). In particular, the typing derivation of the term

$$\lambda a. \lambda b. \langle a, b \rangle$$

can be seen as a deduction tree proving  $A \rightarrow B \rightarrow A \wedge B$ ; as the following diagram shows, in which terms are colored in **red** and types are colored in **blue**.

$$\frac{\frac{\frac{a :: A \quad b :: B}{\langle a, b \rangle :: A \times B} (pair)}{\lambda b. \langle a, b \rangle :: B \rightarrow A \times B} (abs)}{\lambda a. \lambda b. \langle a, b \rangle :: A \rightarrow B \rightarrow A \times B} (abs)$$

Furthermore, under this interpretation, **simplification rules are precisely  $\beta$ -reduction rules**. This makes execution of  $\lambda$ -calculus programs correspond to proof simplification on natural deduction. The Curry-Howard correspondence is then not only a simple bijection between types and propositions, but a deeper isomorphism regarding the way they are constructed, used in derivations, and simplified.

*Example 3* (Curry-Howard simplification example). As an example of this duality, we will write a proof/term of the proposition/type  $A \rightarrow B + A$  and we are going to simplify/compute it using proof simplification rules/ $\beta$ -rules. Similar examples can be found in [Wad15].

We start with the following derivation tree; in which terms are colored in **red** and types are colored in **blue**

$$\begin{array}{c}
\frac{b :: [A + B] \quad \frac{c :: A}{\text{inr } c :: B + A} (\text{inr}) \quad \frac{c :: B}{\text{inl } c :: B + A} (\text{inl})}{\text{case } b \text{ of } [c].\text{inr } c; [c].\text{inl } c :: B + A} (\text{case}) \\
\frac{\text{case } b \text{ of } [c].\text{inr } c; [c].\text{inl } c :: B + A}{\lambda b.\text{case } b \text{ of } [c].\text{inr } c; [c].\text{inl } c :: A + B \rightarrow B + A} (\text{abs}) \quad \frac{a :: A}{\text{inl } a :: A + B} (\text{inl}) \\
\frac{\lambda b.\text{case } b \text{ of } [c].\text{inr } c; [c].\text{inl } c :: A + B \rightarrow B + A \quad \text{inl } a :: A + B}{\lambda a.(\lambda b.\text{case } b \text{ of } [c].\text{inr } c; [c].\text{inl } c) (\text{inl } a) :: B + A} (\text{app}) \\
\frac{\lambda a.(\lambda b.\text{case } b \text{ of } [c].\text{inr } c; [c].\text{inl } c) (\text{inl } a) :: B + A}{\lambda a.(\lambda b.\text{case } b \text{ of } [c].\text{inr } c; [c].\text{inl } c) (\text{inl } a) :: A \rightarrow B + A} (\text{abs})
\end{array}$$

which is encoded by the term  $\lambda a.(\lambda c.\text{case } c \text{ of } [a].\text{inr } a; [b].\text{inl } b) (\lambda z.\text{inl } z)$ . We apply the simplification rule/ $\beta$ -rule of the implication/function application to get

$$\begin{array}{c}
\frac{z :: A}{\text{inl } z :: A + B} (\text{inl}) \quad \frac{a :: A}{\text{inr } a :: B + A} (\text{inr}) \quad \frac{b :: B}{\text{inl } b :: B + A} (\text{inl}) \\
\frac{\text{case } (\text{inl } z) \text{ of } [a].\text{inr } a; [b].\text{inl } b :: B + A}{\lambda z.\text{case } (\text{inl } z) \text{ of } [a].\text{inr } a; [b].\text{inl } b :: A \rightarrow B + A} (\text{case}) \\
\frac{\lambda z.\text{case } (\text{inl } z) \text{ of } [a].\text{inr } a; [b].\text{inl } b :: A \rightarrow B + A}{\lambda z.\text{case } (\text{inl } z) \text{ of } [a].\text{inr } a; [b].\text{inl } b :: A \rightarrow B + A} (\text{abs})
\end{array}$$

which is encoded by the term  $\lambda a.\text{case } (\text{inl } a) \text{ of } (\text{inr}) (\text{inl})$ . We finally apply the case simplification/reduction rule to get

$$\frac{\frac{a :: A}{\text{inr } a :: B + A} (\text{inr})}{\lambda a.\text{inr } a :: A \rightarrow B + A} (\text{abs})$$

which is encoded by  $\lambda a.(\text{inr } a)$ .

On the chapter on [Mikrokosmos](#), we develop a  $\lambda$ -calculus interpreter which is able to check and simplify proofs in intuitionistic logic. This example could be checked and simplified by this interpreter as it is shown in image [1](#).
